Discovery and characterization of two aminoacid substitution variants of RNase S and their implications on metastasis. In order to provide more human cancer data for an in silico method to identify cancer-related genes, we have used the method to screen related protein sequences and obtained a new set of proteins that are probable candidates for metastasis in the early phase. We then characterized two proteins as human pancreatic ribonuclease S (RNase S) and one as rat RNase S-like (rRNase S-l). RNase S and rRNase S-l aminoacid (aa) substitutions were found in human tumor tissues with metastatic potential. One was pancreatic cancer and the other was colonic cancer. We also analyzed a third cancer tissue in which we identified a substitution variant (A in aa 307) that confers metastasis. Immunohistochemical analysis showed that the cancer with the substitution variant (A in aa 307) had similar degree of expression of the RNase S protein compared with the cancer with the wild-type RNase S. These results suggest that RNase S may play a role in the early stage of cancer progression, as well as in the final phase of metastasis. It means "we don't take any", which is closer to fungibility than block chain. ~~~ salawat It does mean "no transaction fees" because the block chain is credit-based. If the transaction is too small to have its own block, it simply passes through without any mechanism for rejecting it. It is more than that. The chain is actually vast, and difficult enough to manage one might argue Bitcoin is a form of monotoring. Whether or not Bitcoin is trustless is another issue entirely. Whether or not transactions can be sent to a destination, and proven to have been signed, with a trustless system, is another. There are already no fees for services off the
