Plural and singular in English and Germanic languages: The influence of gender Abstract The grammatical variation between singular and plural forms in many languages is of great interest to a diverse range of disciplines, including linguistics, psychology, and cognitive sciences. So far, research has largely investigated how grammatical number affects linguistic processing and has revealed some well-established differences between these two grammatical categories. For instance, grammatical number has been shown to affect various aspects of language processing like word recognition, morphosyntactic processing, and reference resolution. In the present article, we will focus on gender in English and Germanic languages, but our theoretical framework is compatible with other grammatical categories, as well as with other languages. We will begin by giving a short overview of the research on gender in English and German, before introducing our theoretical approach of a universal grammatical gender, which is based on universal structural constraints on grammatical number, and generalizing to other grammatical categories.

Q: Get a range of values from a String with regex I'm trying to parse a string using multiple regex patterns, but at some point I need to "get a range" of values from a string, say [2, 5]. For example, the string is like this: "Habbo, Some Room, [2, 5], Building, Room A" And I need to get a list of the results of the regex pattern: "Habbo", "Some Room", "[2, 5]", "Building", "Room A" I used to do this with regex: `[a-zA-Z]+\s+\[(\d+),?(\d+)\]\s*[a-zA-Z]+` But it doesn't do what I wanted. My idea was, if I see the string beginning with "Habbo" (which I mean as the opening start position for the regex), I append the string beginning with "Habbo" to the List
